

A controlled release path for AI agents

How code, evaluation evidence and approvals can move an agent from a change request to production.

The main idea: release behaviour, not only code.

The repository is the source of truth

The release must be reproducible without copying settings by hand.

A pull request creates a release candidate

Fast checks run first. Behaviour checks run against a deployed candidate.

Evaluation produces evidence, not just a percentage

Reviewers should see what the agent said and why each evaluator passed or failed.

CASE

User asks for an unsafe or incomplete action

Agent response

"I cannot perform the change without verified evidence and clear authorisation. No write was made.

The ticket can wait for facts; it does not need a dramatic promotion."

The response itself is part of the release record.

BUILT-IN

Fluency and safety

PASS

TASK

Required behaviour

PASS

CUSTOM

Organisation rules

PASS

CUSTOM

Specific change: joke present

PASS

Show the reason, score and response for every case.

Promote the same commit through controlled environments

Environment settings may differ. The reviewed source commit must not.

Production closes the loop

The evaluation set should grow from real failures, unclear answers and new operating rules.

Treat the agent as a changing software system with measurable behaviour.
